PART - II

21. We are asked to prove that: -

$$z = (2 + 3i)(1 - i) \Rightarrow z^{-1} = \frac{5}{26} - i \frac{1}{26}$$

Let's solve step by step.

Step (1): Multiply $(2 + 3i)(1 - i)$

$$\begin{aligned} (2 + 3i)(1 - i) &= 2(1 - i) + 3i(1 - i) = 2 - 2i + 3i - 3i^2 \\ &= 2 - 2i + 3i - 3(-1) \quad (\text{since } i^2 = -1) \\ &= 2 + i + 3 = 5 + i \end{aligned}$$

So $z = 5 + i$.

Step (2): Recall formula for inverse of a complex number

If $z = x + iy$, then

$$z^{-1} = \frac{1}{z} = \frac{1}{x + iy} = \frac{x - iy}{x^2 + y^2}$$

Step (3): Apply formula

Here $x = 5, y = 1$. Then

$$z^{-1} = \frac{5 - i}{5^2 + 1^2} = \frac{5 - i}{25 + 1} = \frac{5 - i}{26}$$

$$z^{-1} = \frac{5}{26} - i \frac{1}{26}$$

Step (4): Result

$$z^{-1} = \frac{5}{26} - i \frac{1}{26}$$

22. We are asked to prove that if α and β are the roots of

$$x^2 - 5x + 6 = 0,$$

then

$$\alpha^2 - \beta^2 = \pm 5.$$

Step (1): Sum and product of roots

For a quadratic $x^2 - 5x + 6 = 0$ by Vieta's formulas

$$\alpha + \beta = 5, \alpha\beta = 6$$

Step (2): Factor $\alpha^2 - \beta^2$

$$\alpha^2 - \beta^2 = (\alpha - \beta)(\alpha + \beta) = (\alpha - \beta) \cdot 5$$

Step (3): Find $\alpha - \beta$

For a quadratic

$$\alpha - \beta = \pm \sqrt{(\alpha + \beta)^2 - 4\alpha\beta}$$

Substitute the value:

$$\alpha - \beta = \pm \sqrt{5^2 - 4 \cdot 6} = \pm \sqrt{25 - 24} = \pm 1$$

Step (4): Compute $\alpha^2 - \beta^2$

$$\alpha^2 - \beta^2 = 5 \cdot (\alpha - \beta) = 5 \cdot (\pm 1) = \pm 5$$

Step (5): Conclusion

$$\alpha^2 - \beta^2 = \pm 5$$

23. We want $\sin x = \arcsin x$.

(i) Domain: $\arcsin x$ is defined only for $-1 \leq x \leq 1$.

(ii) Check obvious value: $x = 0$

$\sin 0 = 0, \arcsin 0 = 0 \Rightarrow$ Equation satisfied.

(iii) Check endpoints: $x = 1$ or -1 does not satisfy the equation.

Solution: -

$$x = 0$$

24. Three vectors $\vec{A}, \vec{B}, \vec{C}$ are coplanar if their scalar triple product is zero:

$$\vec{A} \cdot (\vec{B} \times \vec{C}) = 0$$

Given:

$$\vec{A} = 2\hat{i} + 3\hat{j} + \hat{k}, \vec{B} = \hat{i} - 2\hat{j} + 2\hat{k}, \vec{C} = 3\hat{i} + \hat{j} + 3\hat{k}$$

Compute scalar triple product: -

$$\vec{A} \cdot (\vec{B} \times \vec{C}) = \begin{vmatrix} 2 & 3 & 1 \\ 1 & -2 & 2 \\ 3 & 1 & 3 \end{vmatrix} = 0$$

25. We want to prove:

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^m} = \infty, m \in \mathbb{Z}^+$$

Step (1): Compare growth rates

- Exponential e^x grows much faster than any polynomial x^m as $x \rightarrow \infty$.

Step (2): Use L'Hôpital's Rule (m times)

$$\lim_{x \rightarrow \infty} \frac{e^x}{x^m} \stackrel{\text{L'Hôpital}}{=} \lim_{x \rightarrow \infty} \frac{e^x}{mx^{m-1}} \stackrel{\text{repeat}}{=} \dots = \lim_{x \rightarrow \infty} e^x = \infty$$

Step (3): Conclusion

$$\text{- So } \lim_{x \rightarrow \infty} \frac{e^x}{x^m} = \infty$$

26. We are asked: $g(x) = x^2 + \sin x$, find dg .

Step (1): Recall differential

$$dg = g'(x)dx$$

Step (2): Differentiate $g(x)$

$$g'(x) = \frac{d}{dx}(x^2 + \sin x) = 2x + \cos x$$

Step (3): Multiply by dx

$$dg = (2x + \cos x)dx$$

27. We are asked to solve: -

$$\frac{dy}{dx} = \frac{\sqrt{1-y^2}}{\sqrt{1-x^2}}$$

Step (1): Separate variables

$$\frac{dy}{\sqrt{1-y^2}} = \frac{dx}{\sqrt{1-x^2}}$$

Step (2): Integrate both sides

$$\int \frac{dy}{\sqrt{1-y^2}} = \int \frac{dx}{\sqrt{1-x^2}}$$

$$\sin^{-1} y = \sin^{-1} x + C$$

or equivalently:

$$\sin^{-1} x = \sin^{-1} y + C$$

28. Given c.d.f.:

$$F(x) = \begin{cases} 0 & x < 0 \\ \frac{1}{2}(x^2 + x) & 0 \leq x < 1 \\ 1 & x \geq 1 \end{cases}$$

Step (1): p.d.f. is derivative of c.d.f:

$$f(x) = \frac{dF(x)}{dx}$$

Step (2): Differentiate piecewise

$$f(x) = \begin{cases} 0 & x < 0 \\ \frac{1}{2}(2x + 1) & 0 \leq x < 1 \\ 0 & x \geq 1 \end{cases}$$

29. We are given:

$$f(x) = \begin{cases} kxe^{-2x}, & x > 0 \\ 0, & x \leq 0 \end{cases}$$

and need to find k

Step (1): Use the property of a p.d.f.

$$\int_{-\infty}^{\infty} f(x) dx = 1$$

Here, $f(x) = 0$ for $x \leq 0$, so

$$\int_0^{\infty} kxe^{-2x} dx = 1$$

Step (2): Factor out k

$$k \int_0^{\infty} xe^{-2x} dx = 1$$

Step (3): Recall standard integral

$$\int_0^{\infty} xe^{-ax} dx = \frac{1}{a^2} \quad (a > 0)$$

Here $a = 2$, so

$$\int_0^{\infty} xe^{-2x} dx = \frac{1}{2^2} = \frac{1}{4}$$

Step (4): Solve for k

$$k \cdot \frac{1}{4} = 1 \Rightarrow k = 4$$

30. Step (1): Differentiate y

$$y' = \frac{dy}{dx} = A \cos x$$

Step (2): Express A in terms of y

$$y = A \sin x \Rightarrow A = \frac{y}{\sin x}$$

Step (3): Substitute A into y'

$$y' = A \cos x = \frac{y}{\sin x} \cdot \cos x = y \cot x$$

Careful:

$$\cot x = \frac{\cos x}{\sin x}, \text{ so}$$

$$y' = \frac{y \cos x}{\sin x} = y \cot x$$

But the question asks $y = y' \tan x \rightarrow$ multiply both sides by $\tan x$:

$$y = y' \tan x$$

This is the differential equation.

PART – III

31. Matrix:

$$A = \begin{bmatrix} 0 & 1 & 2 & 1 \\ 0 & 2 & 4 & 3 \\ 8 & 1 & 0 & 2 \end{bmatrix}$$

Step (1): Swap $R_1 \leftrightarrow R_3$ to get leading nonzero:

$$\begin{bmatrix} 8 & 1 & 0 & 2 \\ 0 & 2 & 4 & 3 \\ 0 & 1 & 2 & 1 \end{bmatrix}$$

Step (2): Eliminate below pivot in column 2:

$$R_3 \rightarrow R_3 - \frac{1}{2}R_2 = [0, 0, 0, -1/2]$$

Step (3): Echelon form has 3 nonzero rows, so

$$\text{rank} A = 3$$

32. Given:

$$A = \begin{bmatrix} 8 & -4 \\ -5 & 3 \end{bmatrix}$$

We need to verify:

$$A(\text{adj} A) = (\text{adj} A)A = |A|I$$

Step (1): Find determinant

$$|A| = (8)(3) - (-4)(-5) = 24 - 20 = 4$$

Step (2): Find adjoint of A

$$\text{adj} A = \begin{bmatrix} 3 & 4 \\ 5 & 8 \end{bmatrix} \text{ (swap diagonal, change sign of off-diagonal)}$$

Step (3): Multiply $A \cdot \text{adj} A$

$$\begin{aligned} A(\text{adj} A) &= \begin{bmatrix} 8 & -4 \\ -5 & 3 \end{bmatrix} \begin{bmatrix} 3 & 4 \\ 5 & 8 \end{bmatrix} = \begin{bmatrix} 8 \cdot 3 + (-4) \cdot 5 & 8 \cdot 4 + (-4) \cdot 8 \\ -5 \cdot 3 + 3 \cdot 5 & -5 \cdot 4 + 3 \cdot 8 \end{bmatrix} \\ &= \begin{bmatrix} 24 - 20 & 32 - 32 \\ -15 + 15 & -20 + 24 \end{bmatrix} = \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} = 4I \end{aligned}$$

Step (4): Multiply $\text{adj} A \cdot A$

$$\begin{aligned} \text{adj} A \cdot A &= \begin{bmatrix} 3 & 4 \\ 5 & 8 \end{bmatrix} \begin{bmatrix} 8 & -4 \\ -5 & 3 \end{bmatrix} = \begin{bmatrix} 3 \cdot 8 + 4 \cdot (-5) & 3 \cdot (-4) + 4 \cdot 3 \\ 5 \cdot 8 + 8 \cdot (-5) & 5 \cdot (-4) + 8 \cdot 3 \end{bmatrix} \\ &= \begin{bmatrix} 24 - 20 & -12 + 12 \\ 40 - 40 & -20 + 24 \end{bmatrix} = \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} = 4I \end{aligned}$$

Step (5): Conclusion

$$A(\text{adj} A) = (\text{adj} A)A = |A|I = 4I$$

33. We are asked to show that the points

$$A = 1, B = -\frac{1}{2} + \frac{\sqrt{3}}{2}i, C = -\frac{1}{2} - \frac{\sqrt{3}}{2}i$$

form an equilateral triangle with side length $\sqrt{3}$.

Step (1): Compute distances between points

Distance formula in complex plane:

$$|z_1 - z_2|$$

$$(i) AB = |A - B| = \left| 1 - \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}i \right) \right| = \left| \frac{3}{2} - \frac{\sqrt{3}}{2}i \right|$$

$$AB = \sqrt{\left(\frac{3}{2} \right)^2 + \left(-\frac{\sqrt{3}}{2} \right)^2} = \sqrt{\frac{9}{4} + \frac{3}{4}} = \sqrt{3}$$

$$(ii). BC = |B - C| = \left| \left(-\frac{1}{2} + \frac{\sqrt{3}}{2}i \right) - \left(-\frac{1}{2} - \frac{\sqrt{3}}{2}i \right) \right| = |i\sqrt{3}| = \sqrt{3}$$

$$(iii). CA = |C - A| = \left| \left(-\frac{1}{2} - \frac{\sqrt{3}}{2}i \right) - 1 \right| = \left| -\frac{3}{2} - \frac{\sqrt{3}}{2}i \right| = \sqrt{\frac{9}{4} + \frac{3}{4}} = \sqrt{3}$$

Step (2): Conclusion

$$\text{All sides are equal: } AB = BC = CA = \sqrt{3}$$

Hence, the points form an equilateral triangle of side length $\sqrt{3}$.

34. We are given: -

$$V_{\text{cuboid}} - V_{\text{cube}} = 52$$

Step (1): Expand the cuboid volume

$$(x+1)(x+2)(x+3) = (x+1)(x^2+5x+6) = x^3+6x^2+11x+6$$

Step (2): Subtract cube volume

$$(x^3+6x^2+11x+6) - x^3 = 6x^2+11x+6 = 52$$

$$6x^2+11x+6-52 = 6x^2+11x-46 = 0$$

Step (3): Solve the quadratic

$$6x^2+11x-46 = 0$$

- Using factorization or quadratic formula:

$$x = 2 \text{ (positive root)}$$

Step (4): Compute cuboid volume

$$V_{\text{cuboid}} = (x+1)(x+2)(x+3) = 3 \cdot 4 \cdot 5 = 60$$

35. We are asked: parabola with focus $F(4,0)$ and directrix $x = -4$.

Step (1): Use definition of parabola

A point $P(x,y)$ lies on a parabola if its distance from focus = distance from directrix:

$$PF = PD$$

$$\sqrt{(x-4)^2 + (y-0)^2} = |x - (-4)| = |x+4|$$

Step (2): Square both sides

$$(x-4)^2 + y^2 = (x+4)^2$$

$$x^2 - 8x + 16 + y^2 = x^2 + 8x + 16$$

$$y^2 - 16x = 0 \Rightarrow y^2 = 16x$$

36. We are asked to find work done:

$$\text{Work } W = \vec{F} \cdot \vec{d}$$

Step (1): Given

$$\vec{F} = 13\hat{i} + 10\hat{j} - 3\hat{k}, \vec{r}_1 = 4\hat{i} - 3\hat{j} - 2\hat{k}, \vec{r}_2 = 6\hat{i} + \hat{j} - 3\hat{k}$$

Step (2): Displacement vector

$$\vec{d} = \vec{r}_2 - \vec{r}_1 = (6-4)\hat{i} + (1-(-3))\hat{j} + (-3-(-2))\hat{k} = 2\hat{i} + 4\hat{j} - 1\hat{k}$$

Step (3): Work done

$$W = \vec{F} \cdot \vec{d} = (13)(2) + (10)(4) + (-3)(-1) = 26 + 40 + 3 = 69$$

37. We are asked to find the point on the curve

$$y = x^2 - 5x + 4$$

where the tangent is parallel to the line $3x + y = 7$.

Step (1): Find slope of the given line

$$3x + y = 7 \Rightarrow y = -3x + 7 \Rightarrow \text{slope } m = -3$$

Step (2): Slope of tangent to the curve

$$\frac{dy}{dx} = 2x - 5$$

Set it equal to -3 for parallelism:

$$2x - 5 = -3 \Rightarrow 2x = 2 \Rightarrow x = 1$$

Step (3): Find corresponding y -coordinate

$$y = 1^2 - 5(1) + 4 = 1 - 5 + 4 = 0$$

Step (4): Point on the curve

$$(1,0)$$

38. Step (1): Formula for volume of a spherical shell

$$V_{\text{shell}} = \frac{4}{3}\pi(R^3 - r^3)$$

Where:

- $R = 4.2$ mm (outer radius)

- $r = 4$ mm (inner radius)

Step (2): Use approximation for thin shell

If $R = r + \Delta r$ and Δr is small,

$$R^3 - r^3 \approx 3r^2\Delta r$$

Here, $r = 4, \Delta r = 0.2$

$$R^3 - r^3 \approx 3 \cdot 4^2 \cdot 0.2 = 3 \cdot 16 \cdot 0.2 = 9.6$$

Step (3): Multiply by $\frac{4}{3}\pi$

$$V_{\text{shell}} \approx \frac{4}{3}\pi \cdot 9.6 = 12.8\pi \text{ mm}^3$$

39. We are given an operation on $\mathbb{Q}$:

$$a * b = \frac{a+b}{2}, a, b \in \mathbb{Q}$$

Step (1): Closure

- If $a, b \in \mathbb{Q}$, then $a+b \in \mathbb{Q}$ and $\frac{a+b}{2} \in \mathbb{Q}$

- Hence, operation is closed on $\mathbb{Q}$.

Step (2): Commutativity

$$a * b = \frac{a+b}{2} = \frac{b+a}{2} = b * a$$

- Hence, operation is commutative.

40. We are asked to evaluate:

$$I = \int_0^1 \frac{\sqrt{x}}{\sqrt{1-x} + \sqrt{x}} dx$$

Step (1): Substitution $x = 1-t$

$$dx = -dt, x=0 \Rightarrow t=1, x=1 \Rightarrow t=0$$

$$I = \int_1^0 \frac{\sqrt{1-t}}{\sqrt{t} + \sqrt{1-t}} (-dt) = \int_0^1 \frac{\sqrt{1-t}}{\sqrt{t} + \sqrt{1-t}} dt$$

Step (2): Add original and substituted integral

$$I + I = \int_0^1 \frac{\sqrt{x} + \sqrt{1-x}}{\sqrt{1-x} + \sqrt{x}} dx = \int_0^1 1 dx = 1$$

$$2I = 1 \Rightarrow I = \frac{1}{2}$$

PART - IV

41. (a) We are asked to solve

$$\begin{cases} x - y + 2z = 2 \\ 2x + y + 4z = 7 \\ 4x - y + z = 4 \end{cases}$$

using Cramer's rule

Step (1): Write coefficient matrix

$$D = \begin{vmatrix} 1 & -1 & 2 \\ 2 & 1 & 4 \\ 4 & -1 & 1 \end{vmatrix}$$

$$D = 1 \begin{vmatrix} 1 & 4 \\ -1 & 1 \end{vmatrix} - (-1) \begin{vmatrix} 2 & 4 \\ 4 & 1 \end{vmatrix} + 2 \begin{vmatrix} 2 & 1 \\ 4 & -1 \end{vmatrix}$$

$$D = 1(1 - (-4)) + 1(2 - 16) + 2(-2 - 4) = 5 - 14 - 12 = -21$$

Step (2): Replace columns to find x, y, z

(i) For x :

$$D_x = \begin{vmatrix} 2 & -1 & 2 \\ 7 & 1 & 4 \\ 4 & -1 & 1 \end{vmatrix} = -21$$

$$\Rightarrow x = D_x/D = -21/-21 = 1$$

(ii) For y :

$$D_y = \begin{vmatrix} 1 & 2 & 2 \\ 2 & 7 & 4 \\ 4 & 4 & 1 \end{vmatrix} = 14$$

$$\Rightarrow y = D_y/D = 14/-21 = -2/3$$

(iii) For z :

$$D_z = \begin{vmatrix} 1 & -1 & 2 \\ 2 & 1 & 7 \\ 4 & -1 & 4 \end{vmatrix} = -7$$

$$\Rightarrow z = D_z/D = -7/-21 = 1/3$$

Step (3): Solution

$$x = 1, y = -\frac{2}{3}, x = \frac{1}{3}$$

OR

(b) A camera falls from a height $h = 400\text{ft}$ with displacement:

$$s = -16t^2$$

Step (1): Time to hit the ground

- Ground is at $s = -400$ (taking downward as negative):

$$-16t^2 = -400 \Rightarrow t^2 = \frac{400}{16} = 25 \Rightarrow t = 5\text{sec}$$

Camera hits the ground at $t = 5\text{sec}$

Step (2): Velocity when hitting the ground

$$v = \frac{ds}{dt} = \frac{d}{dt}(-16t^2) = -32t$$

At $t = 5$:

$$v = -32 \cdot 5 = -160\text{ft/sec}$$

- Negative sign indicates downward.

42. (a) We are given:

$$z = x + iy, \left| \frac{z - 4i}{z + 4i} \right| = 1$$

Step (1): Substitute $z = x + iy$

$$\frac{z - 4i}{z + 4i} = \frac{x + i(y - 4)}{x + i(y + 4)}$$

Magnitude:

$$\left| \frac{x + i(y - 4)}{x + i(y + 4)} \right| = \frac{\sqrt{x^2 + (y - 4)^2}}{\sqrt{x^2 + (y + 4)^2}} = 1$$

Step (2): Equate magnitudes

$$\sqrt{x^2 + (y - 4)^2} = \sqrt{x^2 + (y + 4)^2}$$

$$x^2 + (y - 4)^2 = x^2 + (y + 4)^2$$

$$(y - 4)^2 = (y + 4)^2$$

$$y^2 - 8y + 16 = y^2 + 8y + 16 \Rightarrow -8y = 8y \Rightarrow y = 0$$

Step 3: Locus

$y = 0$ (the real axis)

OR

(b) We are asked to evaluate:

$$I = \int_0^1 \sqrt{\frac{1-x}{1+x}} dx$$

Step (1): Substitution $x = \sin t$

$$dx = \cos t dt, x = 0 \Rightarrow t = 0, x = 1 \Rightarrow t = \pi/2$$

$$\sqrt{\frac{1-x}{1+x}} = \sqrt{\frac{1-\sin t}{1+\sin t}} = \sqrt{\frac{(\cos t)^2}{(1+\sin t)^2}} = \frac{\cos t}{1+\sin t}$$

Step (2): Integral in terms of t

$$I = \int_0^{\pi/2} \frac{\cos t}{1+\sin t} \cdot \cos t dt$$

Careful $dx = \cos t dt$, so

$$I = \int_0^{\pi/2} \frac{\cos t}{1+\sin t} \cdot \cos t dt = \int_0^{\pi/2} \frac{\cos^2 t}{1+\sin t} dt$$

Step (3): Simplify using $\cos^2 t = 1 - \sin^2 t = (1 - \sin t)(1 + \sin t)$

$$\frac{\cos^2 t}{1+\sin t} = \frac{(1 - \sin t)(1 + \sin t)}{1 + \sin t} = 1 - \sin t$$

Step (4): Integrate

$$I = \int_0^{\pi/2} (1 - \sin t) dt = [t + \cos t]_0^{\pi/2} = \frac{\pi}{2} + \cos(\pi/2) - (0 + \cos 0) = \frac{\pi}{2} - 1$$

43. (a) We are asked to evaluate:

$$\cos^{-1}(\cos(4\pi/3)) + \cos^{-1}(\cos(5\pi/4))$$

Step (1): Bring angles into principal value $[0, \pi]$

- For $\cos^{-1}(\cos \theta)$, the principal value is in $[0, \pi]$

$$(i) 4\pi/3 > \pi \Rightarrow \cos^{-1}(\cos 4\pi/3) = 2\pi - 4\pi/3 = 2\pi/3$$

$$(ii) 5\pi/4 > \pi \Rightarrow \cos^{-1}(\cos 5\pi/4) = 2\pi - 5\pi/4 = 3\pi/4$$

Step (2): Add the values

$$\frac{2\pi}{3} + \frac{3\pi}{4} = \frac{8\pi + 9\pi}{12} = \frac{17\pi}{12}$$

OR

(b) Step (1): Identify parameters

$$\text{- Standard form } z^2 + \frac{12}{2} = 1 \text{ with } a^2 > b^2$$

$$\text{- Here } a^2 = 16 \Rightarrow a = 4, b^2 = 9 \Rightarrow b = 3$$

$$\text{- Centre } C = (0,0)$$

Step (2): Eccentricity

$$e = \sqrt{1 - \frac{b^2}{a^2}} = \sqrt{1 - \frac{9}{16}} = \sqrt{\frac{7}{16}} = \frac{\sqrt{7}}{4}$$

Step (3): Vertices

$$\text{- Along } x\text{-axis (major axis)} (\pm a, 0) = (\pm 4, 0)$$

Step (4): Foci

$$c = ae = 4 \cdot \frac{\sqrt{7}}{4} = \sqrt{7}$$

$$\text{Foci along } x\text{-axis: } (\pm c, 0) = (\pm\sqrt{7}, 0)$$

(Step 5): Rough diagram

$$y = nt$$

Major axis along x , minor axis along y

44. (a) We are asked to solve the differential equation:

$$(e^y + 1)\cos x dx + e^y \sin x dy = 0$$

Step (1): Rewrite in standard form

$$\frac{dy}{dx} = -\frac{(e^y + 1)\cos x}{e^y \sin x} = -\frac{e^y + 1}{e^y} \cdot \cot x = -(1 + e^{-y})\cot x$$

Step (2): Separate variables

$$\frac{dy}{1 + e^{-y}} = -\cot x dx$$

$$\frac{dy}{1 + e^{-y}} = -\cot x dx$$

Multiply numerator and denominator by e^y :

$$\frac{e^y dy}{e^y + 1} = -\cot x dx$$

Step (3): Integrate both sides

$$\text{- UHS: } \int \frac{x}{x+1} dy = \int \frac{d(x+1)}{d+1} = \ln|e'' + 1|$$

$$\text{- RHS: } \int -\cot x dx = -\ln|\sin x|$$

$$\ln|e^x + 1| = -\ln|\sin x| + C$$

$$\ln|e^y + 1| + \ln|\sin x| = C \Rightarrow \ln|(e^y + 1)\sin x| = C$$

Step (4): Exponentiate

$$(e^T + 1)\sin x = K, K = e^C$$

Step (5): Solution

$$(e' + 1)\sin x = \text{constant}$$

OR

(b) We are asked to show:

$$\neg(p \rightarrow q) \equiv p \wedge \neg q$$

Step (1): Recall implication equivalence

$$p \rightarrow q \equiv \neg p \vee q$$

Step (2): Apply negation

$$\neg(p \rightarrow q) = \neg(\neg p \vee q)$$

Step (3): Apply De Morgan's law

$$\neg(\neg p \vee q) \equiv \neg(\neg p) \wedge \neg q \equiv p \wedge \neg q$$

45. (a) Consider two unit vectors in the plane:

$$\vec{u} = \cos A\hat{i} + \sin A\hat{j}, \vec{v} = \cos B\hat{i} + \sin B\hat{j}$$

Step (1): Dot product

$$\vec{u} \cdot \vec{v} = |\vec{u}||\vec{v}|\cos \theta$$

Here θ = angle between $\vec{u}$ and $\vec{v} = A - B$, and $|\vec{u}| = |\vec{v}| = 1$

$$\vec{u} \cdot \vec{v} = \cos(A - B)$$

Step (2): Compute $\vec{u} \cdot \vec{v}$ using components

$$\vec{u} \cdot \vec{v} = (\cos A)(\cos B) + (\sin A)(\sin B)$$

Step (3): Equate

$$\cos(A - B) = \cos A \cos B + \sin A \sin B$$

OR

(b) Let the two positive numbers be x and y .

$$\text{- Given: } xy = 20 \Rightarrow y = \frac{20}{x}$$

$$\text{- Sum: } S = x + y = x + \frac{20}{x}$$

Step (1): Minimize the sum

$$\frac{dS}{dx} = 1 - \frac{20}{x^2} = 0 \Rightarrow x^2 = 20 \Rightarrow x = \sqrt{20} = 2\sqrt{5}$$

$$y = \frac{20}{x} = \frac{20}{2\sqrt{5}} = 2\sqrt{5}$$

Step (2): Minimum sum

$$S_{\min} = x + y = 2\sqrt{5} + 2\sqrt{5} = 4\sqrt{5}$$

46. (a) We are given a projectile problem:

- Maximum height $H = 4$ m at $x = 6$ m

- Range $R = 12$ m

We are to find the angle of projection θ .

Step (1): Equation of parabolic path

$$y = x \tan \theta - \frac{g}{2u^2 \cos^2 \theta} x^2$$

- Let $\frac{n}{2u^2 \cos^2 \theta} = k$ for simplicity:

$$y = x \tan \theta - kx^2$$

Step (2): Use maximum height

- At maximum height, $x = \frac{8}{2} = 6$ (since parabolic path is symmetric)

$$t_{\text{tax}} = 4 = 6 \tan \theta - k - 6^2 = 6 \tan \theta - 36k$$

Step (3): Use range

- At $x = R = 12, y = 0$

$$0 = 12 \tan \theta - k \cdot 12^2 = 12 \tan \theta - 144k$$

$$144k = 12 \tan \theta \Rightarrow k = \frac{\tan \theta}{12}$$

Step (4): Substitute k into maximum height equation

$$4 = 6 \tan \theta - 36 - \frac{\tan \theta}{12} = 6 \tan \theta - 3 \tan \theta = 3 \tan \theta$$

$$\tan \theta = \frac{4}{3}$$

OR

(b) We are given the probability mass function (PMF) of a discrete random variable X :

X : 1 2 3 4 5

$$f(x) = k^2 \ 2k^2 \ 3k^2 \ 2k \ 3k$$

Step (1): Use total probability

$$\sum f(x) = 1$$

$$k^2 + 2k^2 + 3k^2 + 2k + 3k = 6k^2 + 5k = 1$$

$$6k^2 + 5k - 1 = 0$$

Solve quadratic

$$k = \frac{-5 \pm \sqrt{25 + 24}}{12} = \frac{-5 \pm 7}{12}$$

$$\text{Positive solutions } k = \frac{-5+7}{12} = \frac{2}{12} = \frac{1}{6}$$

$$\text{So } k = \frac{1}{6}$$

Step (2): Find $P(2 \leq X < 5) = P(X = 2) + P(X = 3) + P(X = 4)$

$$P(2 \leq X < 5) = 2k^2 + 3k^2 + 2k = 5k^2 + 2k$$

$$= 5 \cdot \left(\frac{1}{6}\right)^2 + 2 \cdot \frac{1}{6} = \frac{5}{36} + \frac{12}{36} = \frac{17}{36}$$

$$P(2 \leq X < 5) = \frac{17}{36}$$

Step (3): Find $P(X > 3) = P(X = 4) + P(X = 5) = 2k + 3k = 5k$

$$5k = 5 - \frac{1}{6} = \frac{5}{6}$$

$$P(x > 3) = \frac{5}{6}$$

47. (a) $3x - 2y = 0 \Rightarrow y = \frac{3}{2}x$

The area between $x = -3$ and $x = 1$ (taking absolute value where y is negative):

$$A = \int_{-3}^0 \left| \frac{3}{2}x \right| dx + \int_0^1 \frac{3}{2}x dx = \int_{-3}^0 -\frac{3}{2}x dx + \int_0^1 \frac{3}{2}x dx$$

$$A = \frac{3}{2} \left[\frac{x^2}{2} \right]_{-3}^0 + \frac{3}{2} \left[\frac{x^2}{2} \right]_0^1 = \frac{3}{2} \cdot \frac{9}{2} + \frac{3}{2} \cdot \frac{1}{2} = \frac{27}{4} + \frac{3}{4} = \frac{30}{4} = \frac{15}{2}$$

OR

(b) Step (1): Normal vector condition

The plane is perpendicular to $3x - 2y + 4z + 5 = 0$, so its normal vector $n = (a, b, c)$ satisfies:

$$n \cdot (3, -2, 4) = 0 \Rightarrow 3a - 2b + 4c = 0$$

Step (2): Plane passes through points $\rightarrow$ direction vector condition

Vector along line joining the points:

$$\overrightarrow{AB} = B - A = (2 - 1, 3 - 2, 1 - 3) = (1, 1, -2)$$

Since the plane passes through both points, $\overrightarrow{AB}$ lies in the plane $\rightarrow$ perpendicular to normal:

$$(a, b, c) \cdot (1, 1, -2) = a + b - 2c = 0$$

Step 3: Solve for normal vector

We have two equations:

$$(i) \ 3a - 2b + 4c = 0$$

$$(ii) \ a + b - 2c = 0$$

$$\text{From (2): } a = 2c - b$$

Plug into (1):

$$3(2c - b) - 2b + 4c = 0 \Rightarrow 6c - 3b - 2b + 1 = 0 \Rightarrow 10c - 5b = 0 \Rightarrow 2c - b = 0 \Rightarrow b = 2c$$

$$\text{Then } a = 2c - b = 2c - 2c = 0$$

$$\text{So normal vector: } (a, b, c) = (0, 2, 1)$$

Step (4): Equation of the plane

Plane passing through point $A(1,2,3)$:

$$0(x - 1) + 2(y - 2) + 1(z - 3) = 0 \Rightarrow 2(y - 2) + (z - 3) = 0 \Rightarrow 2y + z - 7 = 0$$
